(MARCH - 2025)

1. Introduction

In today's fast-paced healthcare environment, data-driven decision-making plays a crucial role in improving patient care, optimizing hospital resources, and enhancing overall efficiency. With the increasing availability of electronic health records (EHRs) and hospital management systems, healthcare institutions have access to vast amounts of patient data. However, making sense of this data requires systematic analysis and visualization to extract meaningful insights.

This project, "Healthcare Data Exploration," aims to analyze a hospital dataset to uncover key patterns related to patient demographics, medical conditions, treatment costs, and hospital utilization metrics. By performing exploratory data analysis (EDA) and visualization, we seek to answer essential questions such as:

- What are the most common medical conditions and procedures?
- How does age, gender, and medical history impact hospital stay duration and treatment costs?
- What are the trends in readmission rates and patient satisfaction?
- Are there any correlations between treatment costs, length of stay, and patient outcomes?

To achieve these objectives, this project follows a structured methodology, starting with data preprocessing to ensure quality, followed by EDA and visualization to derive actionable insights. The findings from this analysis can be valuable for hospital administrators, policymakers, and healthcare professionals to enhance patient care strategies and optimize hospital operations.

By leveraging Python and its powerful data science libraries (Pandas, Matplotlib, Seaborn, etc.), this project demonstrates how healthcare data analytics can help improve decision-making and patient outcomes in the medical field.

2. Methodology

The project follows a structured data exploration methodology, ensuring a systematic approach to analyzing the healthcare dataset. The methodology consists of the following steps:

Step 1: Data Collection

• The dataset is sourced from Kaggle's "Hospital Dataset for Practice", containing patient information, medical conditions, and treatment details.

• The dataset is in CSV format, making it suitable for direct processing using Pandas in Python.

Step 2: Data Preprocessing

To ensure data quality and reliability, preprocessing steps are applied:

1. Handling Missing Data:

• Numerical missing values (e.g., Cost, Length_of_Stay) are filled with the median value to maintain data consistency.

• Categorical missing values (e.g., Gender, Condition) are replaced with. "Unknown".

2. Data Type Conversion:

• Convert categorical variables (Gender, Readmission, Outcome) into the appropriate format for analysis.

• Ensure numerical columns are stored correctly to perform mathematical operations.

3.Feature Engineering:

• Create an Age Group column to categorize patients into predefined age ranges (e.g., 0-18, 19-35).

Step 3: Exploratory Data Analysis (EDA)

EDA helps uncover patterns, trends, and relationships in the data:

• Summary Statistics:

• Use describe() to compute mean, median, and standard deviation.

• Demographic Analysis:

• Explore the distribution of Age, Gender, and Conditions.

• Hospital Utilization:

• Analyze Length_of_Stay, Readmission rates, and Cost variations.

• Outcome Analysis: Study the relationship between conditions and patient outcomes.

Step 4: Data Visualization

Visualization helps in understanding key trends and correlations:

1. Bar Plots & Count Plots:
    • Used for Gender distribution, Condition frequency, and Readmission rates.

2.Histograms:
    • Show the distribution of Age and Length of Stay.

3. Scatter Plots:
    • Reveal relationships between Cost and Length of Stay.

4. Heatmaps:
    • Display correlations between numerical variables.

Step 5: Insights & Interpretation

    • Extract key patterns and observations from the analysis.
    • Identify high-risk conditions, costly treatments, and patient satisfaction trends.
    • Provide recommendations for improving hospital efficiency and patient care.

2. Project Implementation

```
import pandas as pd
df = pd.read_csv("hospital data analysis.csv")

# Display basic dataset information
print(df.info())
```

```
#print first 5 rows
print(df.head())

#find if there are any missing values
print(df.isnull().sum())

# Summary statistics
print(df.describe())

# Distribution of age groups
df["Age_Group"] = pd.cut(df["Age"], bins=[0, 18, 35, 50, 65, 100], labels=['0-18',
'19-35', '36-50', '51-65', '65+'])
print(df["Age_Group"].value_counts())

# Count patients by gender
print(df["Gender"].value_counts())

df.value_counts()

print(df["Condition"].value_counts())

import matplotlib.pyplot as plt
import seaborn as sns

plt.figure(figsize=(10, 6))
sns.countplot(y=df["Condition"], order=df["Condition"].value_counts().index,
palette='coolwarm')
plt.xlabel("Count")
plt.ylabel("Disease Type")
plt.title("Distribution of Diseases in Patients")
plt.show()

plt.figure(figsize=(10, 6))
sns.countplot(x=df["Age_Group"], palette='viridis')
plt.xlabel("Age Group")
plt.ylabel("Count")
plt.title("Distribution of Patients Across Age Groups")
plt.show()

plt.figure(figsize=(10, 6))
sns.histplot(df["Length_of_Stay"], bins=20, kde=True, color='purple')
plt.xlabel("Hospital Stay Duration (Days)")
plt.ylabel("Frequency")
plt.title("Distribution of Hospital Stay Durations")
plt.show()

plt.figure(figsize=(10, 6))
```

```
sns.heatmap(df.corr(numeric_only=True), annot=True, cmap='coolwarm',
linewidths=0.5)
plt.title("Correlation Matrix of Healthcare Data")
plt.show()
```

3. Output

```
# Display basic dataset information
print(df.info())
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 984 entries, 0 to 983
Data columns (total 10 columns):
 #   Column          Non-Null Count  Dtype
---  ------          --------------  -----
